## Optimization Problem I

Let us consider the following problem that appears in many image processing and computer vision problems:

We computed a matrix  $\mathbf{A} \in \mathbb{R}^{m \times n}$  out of sensor data, like an image. By theory the matrix  $\mathbf{A}$  must have the singular values  $\sigma_1, \sigma_2, \dots, \sigma_k$ ,  $k \leq p = \min\{m, n\}$ . Of course, in practice  $\mathbf{A}$  does not always satisfy this constraint.

**Problem:** What is the matrix  $\mathbf{A}' \in \mathbb{R}^{m \times n}$  that is closest to  $\mathbf{A}$  (according to the Frobenius norm) and has the required singular values?

**Solution:** Let  $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T$ , then

$$\mathbf{A}' = \mathbf{U} \operatorname{diag}(\sigma_1, \sigma_2, \dots, \sigma_k) \mathbf{V}^T.$$

*A, but without the measurement noise*

## Optimization Problem I

### Example

Our measurements lead to the following matrix:

$$\mathbf{A} = \begin{pmatrix} 11 & 10 & 14 \\ 12 & 11 & -13 \\ 14 & 13 & -66 \end{pmatrix} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T.$$

Let us assume that by theoretical arguments the matrix  $\mathbf{A}$  is required to have a **rank deficiency of one**, and the two non-zero singular values are identical. The matrix  $\mathbf{A}'$  that is closest to  $\mathbf{A}$  w. r. t. the Frobenius norm and fulfills the requirements above is:

$$\mathbf{A}' = \mathbf{U} \text{diag} \left( \frac{71.3967 + 21.7831}{2}, \frac{71.3967 + 21.7831}{2}, 0 \right) \mathbf{V}^T.$$

the singular values 71 and 21 were calculated last lecture

## Optimization Problem II

**Problem:** In image processing we are often required to solve the following optimization problem:

$$\hat{\mathbf{x}} = \arg \min_{\mathbf{x}} \mathbf{x}^T \mathbf{A}^T \mathbf{A} \mathbf{x}, \quad \text{subject to} \quad \|\mathbf{x}\|_2 = 1,$$

or in the extreme:

$$\mathbf{A} \mathbf{x} = 0, \quad \text{subject to} \quad \|\mathbf{x}\|_2 = 1. \quad \text{so } \mathbf{x} \text{ cannot be zero}$$

**Solution:** The solution can be constructed using the rightmost column of  $\mathbf{V}$ .

"use smallest singular value ?"

**Exercise:** Check this!

## Optimization Problem II

### Example

Estimate the matrix  $\mathbf{X} \in \mathbb{R}^{2 \times 2}$  such that for vectors

$$\mathbf{b}_1 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \mathbf{b}_2 = \begin{pmatrix} -1 \\ 2 \end{pmatrix}, \mathbf{b}_3 = \begin{pmatrix} 1 \\ -3 \end{pmatrix}, \mathbf{b}_4 = \begin{pmatrix} -1 \\ -4 \end{pmatrix},$$

the following optimization problem gets solved:

$$\begin{aligned} \sum_{i=1}^4 (\mathbf{b}_i^T \mathbf{X} \mathbf{b}_i)^2 &\rightarrow \min, & \text{subject to} & & \|\mathbf{X}\|_F = 1, \\ \Leftrightarrow & \mathbf{b}_i^T \mathbf{X} \mathbf{b}_i = 0, & i = 1, \dots, 4, & & \|\mathbf{X}\|_F = 1. \end{aligned}$$

## Optimization Problem II

But we want to work with Matrixes, not vectors:  
create linear system of equations

### Example

The objective function is linear in the components of  $\mathbf{X}$ , thus the whole sum can be rewritten in matrix notation:

$$\mathbf{M}\mathbf{x} = \mathbf{M} \begin{pmatrix} x_{1,1} \\ x_{1,2} \\ x_{2,1} \\ x_{2,2} \end{pmatrix} = 0, \quad \text{subject to} \quad \|\mathbf{x}\|_2 = 1,$$

where the **measurement matrix**  $\mathbf{M}$  is built from single elements of the sum.

## Optimization Problem II

### Example

Let us consider the  $i$ -th component:

$$\mathbf{b}_i^\top \mathbf{X} \mathbf{b}_i = \mathbf{b}_i^\top \begin{pmatrix} x_{1,1} & x_{1,2} \\ x_{2,1} & x_{2,2} \end{pmatrix} \mathbf{b}_i = \begin{pmatrix} b_{i,1}^2 & b_{i,1} b_{i,2} & b_{i,1} b_{i,2} & b_{i,2}^2 \end{pmatrix} \begin{pmatrix} x_{1,1} \\ x_{1,2} \\ x_{2,1} \\ x_{2,2} \end{pmatrix}.$$

Using this result we get for the overall measurement matrix:

one row for every observation ( $x_{11}, x_{12}, x_{21}, x_{22}$ )

$$\mathbf{M} = \begin{pmatrix} b_{1,1}^2 & b_{1,1} b_{1,2} & b_{1,1} b_{1,2} & b_{1,2}^2 \\ b_{2,1}^2 & b_{2,1} b_{2,2} & b_{2,1} b_{2,2} & b_{2,2}^2 \\ b_{3,1}^2 & b_{3,1} b_{3,2} & b_{3,1} b_{3,2} & b_{3,2}^2 \\ b_{4,1}^2 & b_{4,1} b_{4,2} & b_{4,1} b_{4,2} & b_{4,2}^2 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & -2 & -2 & 4 \\ 1 & -3 & -3 & 9 \\ 1 & 4 & 4 & 16 \end{pmatrix}$$

now SVD of  $\mathbf{M}$

## Optimization Problem II

search for the element with the smallest singular value - the corresponding column in  $V$  gives us the solution for  $x$

### Example

The nullspace of  $M$  can be computed by SVD and yields the required matrix:

$$\mathbf{x} = \begin{pmatrix} 0 & -0.7071 \\ 0.7071 & 0 \end{pmatrix},$$

4 Elements from one column vector in  $V$

which satisfies  $\|\mathbf{x}\|_F \approx 1$ .

This was how we solved a nullspace problem using a SVD.

## Take Home Messages

- For a theoretically known rank, we can compute a best approximation of a matrix computed from measurements using SVD. [the first example with the noisy data](#)
- SVD can be applied to many optimization problems (see also next unit).
- When it comes to optimization, always check if you can solve it with SVD.
